The invention pertains to devices for storing gases and fluids under pressure. More

particularly, the invention relates to pressure vessels that are formed out of flexible materials

and that can be made to conform to a variety of shapes.

Background of the Invention

Typically, pressure vessels capable of containing liquids or gases at significant

pressures have involved fixed shape cylinders or spheres formed of high-strength metals such

as steel or aluminum. Such pressure vessels, while successful for their designed applications,

involve a number of problems. First, such metallic cylinders are relatively heavy compared to

the gases or fluids that they contain. Second, pressure cylinders contain all of the gas or liquid

in a single space. Should the vessel rupture, the entire vessel is destroyed, often with a violent

explosion sending shards of metal in all directions. Third, metallic cylinders have a definite

shape and cannot be adapted to fit readily in many space-constrained applications. The

present invention involves a number of small cells of an elongated tubular shape linked to
